Acknowledgments

Our thanks go to Joyce Wu and Traffic China for providing the tissue samples and associated data. This work was funded by the CCSBT and CSIRO Oceans and Atmosphere.

1 Introduction

CSIRO has developed and refined a specific DNA assay for identification of individual *Thunnus* species and skipjack tuna for widespread commercial application (e.g. Chain of Custody for market certification and Catch Documentation Schemes for tuna RFMOs) as part of a strategic research program on Next Generation Sequencing methods for fisheries monitoring assessment and management (Davies and Grewe 2015; Davies et al. 2015; Grewe et al., 2016). The assay will clearly and reliably distinguish among the primary sashimi-grade species of tuna (southern bluefin tuna, Atlantic bluefin tuna, Pacific/Northern bluefin tuna, bigeye tuna and yellowfin tuna) as well as albacore and skipjack.

CSIRO was approached by Traffic International to provide specific identifications of tissue samples collected from a range of restaurants in Shanghai and Beijing, China, as part of a larger review and trade study on the presence of SBT in Chinese seafood markets commissioned by CCSBT (Anon., 2015). This report summarises the work undertaken and the results of species identification of the samples provided by Traffic International.

2 Objectives

1. Extract the DNA from 100 tissue samples using standardised protocols and profile for species identification.
2. Validate the species ID test for a subset of samples using the Genotyping-by-Sequencing approach (ddRAD).

3 Methods

Sampling collection

A total of 200 muscle tissue samples from sashimi-grade tunas were purchased from sushi restaurants by TRAFFIC China. Sampling was stratified across cities, months and price category of restaurants (Table 1) in an attempt to provide as representative sample of the product being sold as sashimi grade tuna in the same retail markets as an earlier 2012 study. The samples were all collected from restaurants in Beijing and Shanghai, preserved in RNA-Later following standard protocols and transported to CSIRO.

DNA extraction

DNA was extracted from a 10mg sub-sample of tissue from 199 samples. A bead-based extraction protocol (Machery Nagel Nucleomag) kit was used on an Eppendorf EP motion robot to produce a 150uL archive solution and 50uL working stock of DNA in micro-titre format plates. Archive plates of extracted DNA are stored in dedicated -80°C freezers at CSIRO Hobart. The working stock plates

of extracted DNA were shipped to Diversity Arrays Technology (DArT) in Canberra for genotype sequencing of approximately 5000 single nucleotide polymorphism (SNP) loci.

Table 1. Summary of sampling design for estimating proportion of tuna species occurring in sushi restaurants in Beijing and Shanghai in two rounds of sampling in January and March 2016. One sashimi sample was purchased from each restaurant in each price class sampled in each month. Price classes were: 0-100, 101-200, 201-300, 301-400, 400-500, >500.

CITY	MONTH	PRICE CLASS	# RESTAURANTS
Beijing	Jan	5	10
	Mar	5	10
Shanghai	Jan	5	10
	Mar	5	10
Total			200

DNA Profile Analysis

DNA profiles consisted of information collected from 5000 SNP loci for each individual. Genetic distances (i.e. percent difference between two individuals) were calculated for pairwise comparisons of all Traffic samples as well as comparisons to DNA profiles from control samples of known 8 *Thunnus* and Skipjack tuna species previously genotyped by CSIRO. Sequencing artefact errors on the Illumina sequencer occur at 1% or less frequency and thus individuals with less than 1% differences were considered to be samples of the same individual. Percent sequence differences of 2-3% were considered conspecifics and assigned the identification of the matching control species.

4 Results and Discussion

A total of 199 individual DNA profiles were obtained using 5000 SNP loci. Based on percent differences in SNP sequence, individuals were unambiguously classified as belonging to skipjack or one of eight *Thunnus* species (Table 2). Members of identified species groups had percent sequence differences that ranged between 2-3% while species mis-matches had observed percent sequence differences greater than 5%. These clear ranges of percent differences ensured very high probability of correct assignment to species.

Bigeye tuna was the most frequent species found at 35% of the 199 fish analysed. The three bluefin species were present at lower frequencies: Pacific bluefin (28%), Atlantic bluefin (17%) and southern bluefin (13%).

Southern bluefin samples were almost all sampled in Shanghai (Table 3). Only one southern bluefin was sampled in Beijing. And, interestingly, the large majority of southern bluefin samples were in the lowest price class, 0-100 (Table 4), with the small number of samples in high prices classes being for belly meat.

Yellowfin was the least common species present at only 7% of the total sample, while the remaining species (skipjack, albacore, blackfin, and longtail tuna) were not present in the tissues sampled.

Indicative of the power of the genotyping method, tissue from 6 individual fish were identified as having been sampled at more than one restaurant (Table 5). This result may not be surprising if the duplicate samples were from a single large fish which had been distributed among restaurants.

Table 2. Summary of species identification results from 199 tissue samples from sushi restaurants in Beijing and Shanghai, China. ABT = Atlantic bluefin tuna, PBT = Pacific bluefin tuna, BET = bigeye tuna, SBT = southern bluefin tuna, YFT = yellowfin tuna, ALB = albacore tuna, BLK = blackfin tuna, LOT = longtail tuna and SKJ = skipjack tuna.

SPECIES ID	COUNT	PROPORTION
BET	70	0.35
PBT	55	0.28
ABT	34	0.17
SBT	26	0.13
YFT	14	0.07
ALB	0	0.00
BLK	0	0.00
LOT	0	0.00
SKJ	0	0.00
Total	199	1.00

Table 3. Summary of the number of southern bluefin tuna identified in samples collected by city and sampling month.

5 Summary

The results demonstrate that the ddRAD method used here can clearly and unambiguously identify individual tuna species, including southern bluefin tuna with a high degree of accuracy and consistency. Furthermore, it was possible to identify individual fish that were sampled multiple times among different restaurants during the relatively short period of the study, further demonstrating the power of these methods for identifying and or tracking product through the supply chain.

In terms of southern bluefin tuna, the results demonstrate:

- SBT is being sold in retail sushi restaurants in China, representing ~13% of sales in the two major cities during the short period of this study.
- SBT appears to be much more common in the Shanghai market and, predominantly, in the lower price class of restaurant. Although there were examples of it being sold in mid to higher tier classes of restaurant. For the period of the study it constituted ~25% of the sashimi grade tuna sold through sushi restaurants in Shanghai.
- It is generally not being sold as southern bluefin tuna. The most common retail name being “Bluefin tuna” and “Tuna Sashimi”.

Naturally, the somewhat restricted scope of the sampling (the two major cities and two months in the first quarter of 2016) and the strong difference in the presence of SBT between Shanghai (26 observations) and Beijing (one occurrence) means some care needs to be taken in extrapolating these results to the presence of SBT in the wider Chinese market. However, these results and the ancillary data collected by Traffic China as part of the sampling protocols for the study, indicate that SBT represents a substantial proportion of the sashimi market in Shanghai (at least), that it is rare for it to be transparently identified as SBT in the retail market, and there are a range of stated sources of the product being sold in restaurants.

AT CSIRO, WE DO THE
EXTRAORDINARY EVERY DAY

We innovate for tomorrow and help
improve today – for our customers, all
Australians and the world.

Our innovations contribute billions of
dollars to the Australian economy
every year. As the largest patent holder
in the nation, our vast wealth of
intellectual property has led to more
than 150 spin-off companies.

With more than 5,000 experts and a
burning desire to get things done, we are
Australia's catalyst for innovation.

CSIRO. WE IMAGINE. WE COLLABORATE.
WE INNOVATE.
