#### 要旨

本文書は、CCSBT の管理方式に用いられるミナミマグロの資源指数であるコア船 CPUE についてまとめたものである。データ準備、GLM を用いた CPUE 標準化、エリア重み付けについて記述する。データは 2017 年にまで更新した。2017 年の指数は、ベース GLM モデルによる W0.8 及び W0.5 において、この 10 年間の平均より高く、近年 3 年間は高い水準にある。

#### Summary

This paper summarizes the core vessel CPUE which is an abundance index of southern bluefin tuna used in the Management Procedure of CCSBT. It explains data preparation, CPUE standardization using GLM, and area weighting. The data were updated up to 2017. The index values in 2017, in W0.8 and W0.5 by the base GLM model, are higher than the average over the past 10 years, and those are high in recent three years.

## Introduction

The stock management of southern bluefin tuna *Thunnus maccoyii* in CCSBT entered a new era with the agreement and implementation of the Management Procedure (MP) in 2011. The adapted MP in CCSBT determines TAC by the pre-specified rule using longline CPUE and aerial survey index, so that those indices should be evaluated with high transparency. However, because the shot-by-shot data of Japanese longline is critically important intellectual property for fishermen, Japanese government is not able to open it to CCSBT scientists. Therefore, we explain data preparation and indices in detail in this paper, and try to ensure transparency and evaluation.

## Data preparation

The dataset used was created from shot-by-shot records of Japanese longline from Japan (1986-2017), Australia (RTMP data; 1989-2005), and New Zealand (Joint venture; 1990-2015). New Zealand joint venture with Japanese longline vessels was not implemented in 2016. The data from Japan were based on the logbook data, except that RTMP data were used for the most recent years if logbook data were not yet available and RTMP data of the vessel were available. Note that data of operations especially for non-SBT targeting will be added to the dataset one or two years later when logbook data become available.

The dataset was limited to the CCSBT statistical areas between Area 4 and Area 9 and months between April and September. Because there was no Japanese vessel chartered in New Zealand since 2016, data in Area 5 and Are 6 were insufficient. The data in Area 5 and Area 6 were combined in Area 4 and Area 7, respectively (Itoh 2017). Since we found that NZ and South African joint venture ships were mistakenly included in past catch data in Japan, we created a dataset excluding duplication in 2018 (Itoh 2018). In this data analysis, the newly created data set is used.

CPUE was defined as the number of SBT for age 4 and older (age 4+) caught per 1000 hooks. Proportion of age 4+ by 5x5 degree square and month was calculated from the CCSBT catch-at-age database which added catch-at-age data made by Japan this year for 2016 and 2017.

Vessels which caught a large number of SBT (called “core vessels”) were selected with a rule of  $x$  (top rank of SBT catch in a year) = 56 and  $y$  (number of years in the top ranks) = 3. A subset of vessels with a total data records of 185,284 were extracted from entire vessels (Table 1). The number of core vessels chosen ranged from 35 to 106 each year.

For reference, Fig. 1a and Fig.1b show the number of area operated in terms of 5x5-degree / month, 1x1-degree / month and the number of 1x1-degree squares in 5x5-degree square for all operations and operations with positive SBT (age 4+) catch, respectively.

The following modifications were made to the dataset before CPUE standardization:

deleted the records of the operations in south of 50 degree South; and deleted records for operations with extremely high CPUE (>120) as outliers. The shot-by-shot data were aggregated by 5x5 degrees in the month. Aggregated data of little effort (< 10,000 hooks) had been deleted.

### CPUE standardization

CPUE were standardized in GLM using SAS (version 9.4). Small constant of 0.2, which was 10% of the nominal CPUE, was added to CPUE of age 4+ before log transformation (Nishida and Tsuji 1998).

Base series:

$$\log(CPUE+0.2) = Intercept + Year + Month + Area + Lat5 + BET\_CPUE + YFT\_CPUE + (Month*Area) + (Year*Lat5) + (Year*Area) + Error;$$

Two additional CPUE series were made for monitoring purpose of the status of the stock and MP implementation.

Monitoring series 1 (Reduced base model):

$$\log(CPUE+0.2) = Intercept + Year + Month + Area + Lat5 + BET\_CPUE + YFT\_CPUE + (Month*Area) + Error;$$

Monitoring series 2: Same procedure as applied in Base series, but the data used were prepared at the shot-by-shot daily level, not the aggregated 5x5-degree/month level.

Estimated parameter values for Base case are shown in Table 2. The ANOVA statistics for the three cases are shown in Table 3. The standardized CPUE (ls-mean) and QQ plots of the residuals are shown in Fig.2 and Fig. 3.

AIC and BIC were calculated for the base model and the reduced base model nested with each other. The base model is selected from the viewpoint of AIC, but not in BIC (Table 4).

### Area weighted standardized CPUE

Using the estimated parameters obtained from CPUE standardization by GLM, the Constant Square (CS) and Variable Square (VS) abundance indices were computed by the following equations:

$$CS_{4+,y} = \sum_m \sum_a i(AI_{CS})_{(1969-present)} [\exp(Intercept + Year + Month + Area + Lat5 + BET\_CPUE + YFT\_CPUE + (Month*Area) + (Year*Lat5) + (Year*Area) + \sigma^2/2) - 0.2]$$

$$VS_{4+,y} = \sum_m \sum_a \sum_l (AI_{VS})_{ymal} [\exp(Intercept + Year + Month + Area + Lat5 + BET\_CPUE + YFT\_CPUE + (Month*Area) + (Year*Lat5) + (Year*Area) + \sigma^2/2) - 0.2]$$

where

- $CS_{4+,y}$  is the CS abundance index for age 4+ and y-th year,
- $VS_{4+,y}$  is the VS abundance index for age 4+ and y-th year,
- $(AI_{CS})_{(1969\text{-present})}$  is the area index of the CS model for the period 1969-present,
- $(AI_{VS})_{ymal}$  is the area index of the VS model for y-th year, m-th month, a-th SBT statistical area, and l-th latitude,
- $\sigma$  is the mean square error in the GLM analyses,

Then, w0.5 and w0.8 (B-ratio and geostat proxies) were calculated using the equation below.

$$I_{y,a} = wCS_{y,a} + (1-w)VS_{y,a}$$

The area weighted CPUE value in the latest year (2017), which was mainly from RTMP data and targeting on SBT, was corrected from the average ratio of CPUEs between RTMP and Logbook data over the recent three years according to the agreement in the CPUE web-meeting held in March 2010. The constant was set as 1.0 because the average value over three years exceeds 1.0 (ratio Logbook based CPUE in W0.8 / RTMP based CPUE in W0.8 in the core vessel dataset<sup>1</sup>).

The area weighted CPUE series between 1986 and 2017 were calibrated to the historical time series since 1969 based on the agreed method (SAG9 Report in 2008, attachment 5) derived from the GLM model using data of all vessels described in Nishida and Tsuji (1998). At the 3<sup>rd</sup> OMMP Technical meeting held in Seattle in 2010, it was agreed that the pre-1986 series used in MP implementation will be fixed at the value estimated based on data to 2008 only. Calibration would thus in future always be based upon the 1986-2008 points of this series.

Calculated area weighted standardized CPUEs are shown in Table 5 and Fig. 4. The relative index values of W0.8 in 2017 using the base GLM model (1.294) is high as 137% of the average (0.945) in the past 10 years. That of W0.5 in 2017 (0.927) is high as 134% of the average (0.691) in the past 10 years.

The trends of the indices between the GLM model (Base vs Reduced Base) were similar to each other but different since 2010. The differences between the two GLM models were interaction terms of *Year\*Lat5* and *Year\*Area* which were included in Base but not included in Reduced Base. The nominal CPUE by year and latitude in five degrees are

---

<sup>1</sup> In order to prevent a lack of data for interaction terms, the threshold to be deleted for the little effort was lowered to 1000 instead of 10,000.

shown in Fig. 5. The year trends were different by latitude, such as nominal CPUE since 2010 were much higher than in the 1990s in 40S and 45S, but it was similar in 35S except 2015. The nominal CPUE by year and Area are shown in Fig. 6. The year trends were different by Area, such as nominal CPUE since 2010 were much higher than in the 1990s in Area 7 and Area 9, but similar or lower in other Areas. These different trends were taken into account in the Base model, but not in Reduced Base model. As a result, differences in the indices may occur.

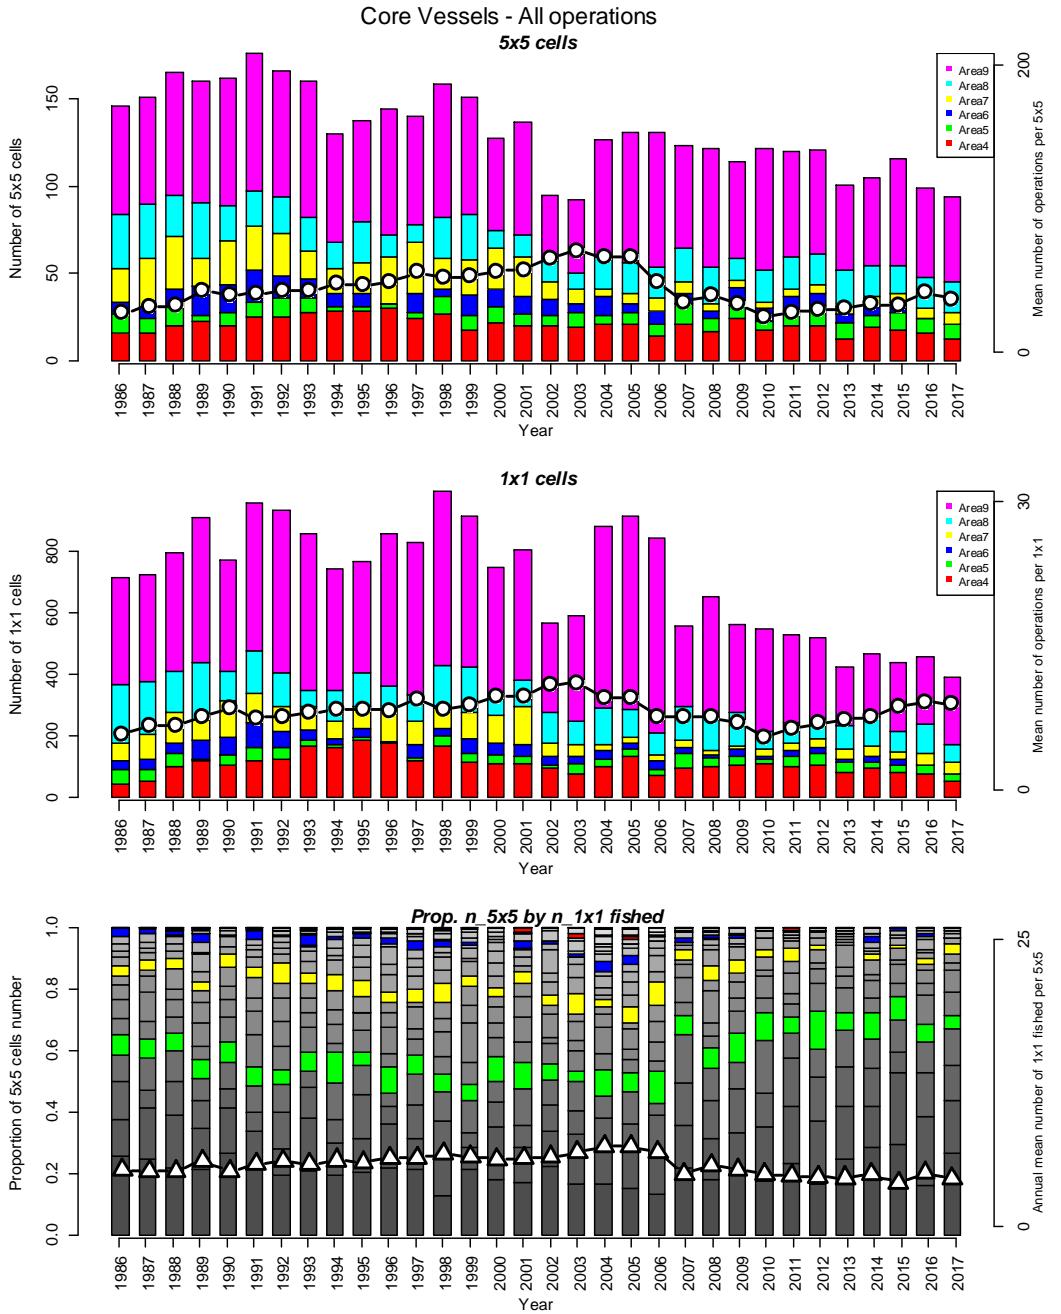

Fig. 1a. Number of cells in the core vessel for all operations.

(Top panel) Bar represents the number of 5x5 degrees square and month (cell) where fishing operated by CCSBT statistical area and refer to left side y-axis. Line with circle plot represents the mean annual number of operations per cell and refer to right side y-axis. (Middle panel) Bar represents the number of 1x1 degree square and month (cell) where fishing operated by CCSBT statistical area and refer to left side y-axis. Line with circle plot represents the mean annual number of operations per cell and refer to right side y-axis. (Bottom panel) Composition of frequency for the number of 1x1 degree square and month cells operated in a 5x5 degree squares and month cell. Refer to left side y-axis. The grey band is one of 25 cells and that at top is 25 of 25 cells, and every five is colored. Line with triangle represents the mean number of 1x1 month cells operated in a 5x5 month cell and refer to right side y-axis.

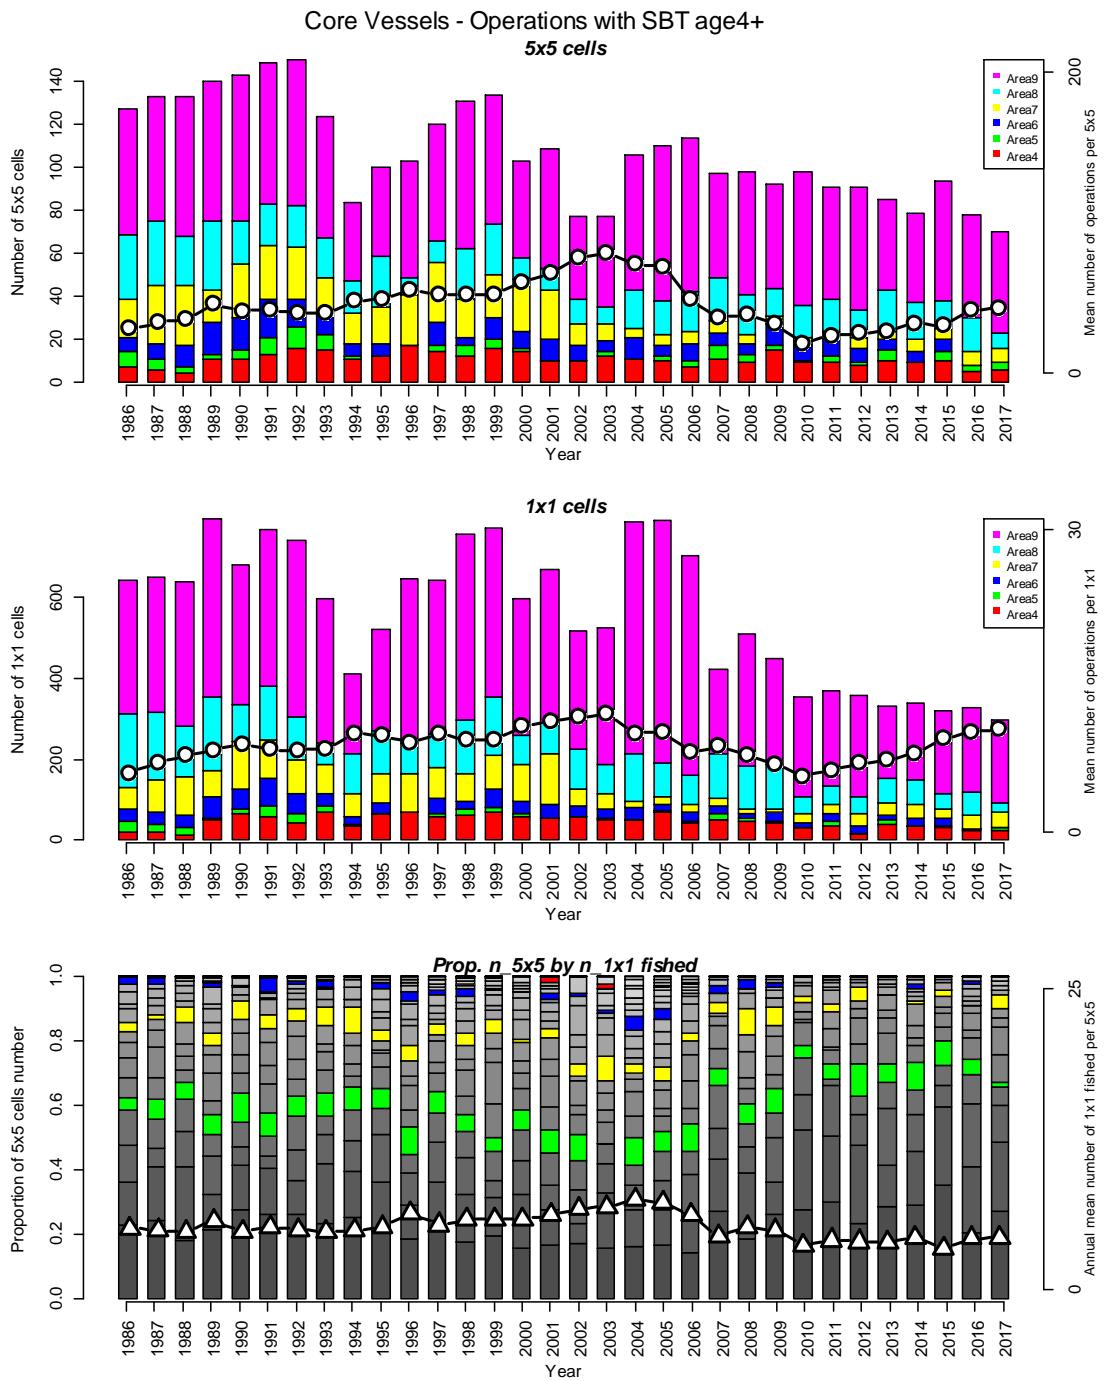

Fig. 1b. Number of cells in the core vessel for SBT 4+ catch positive. See explanation in Fig. 1a.

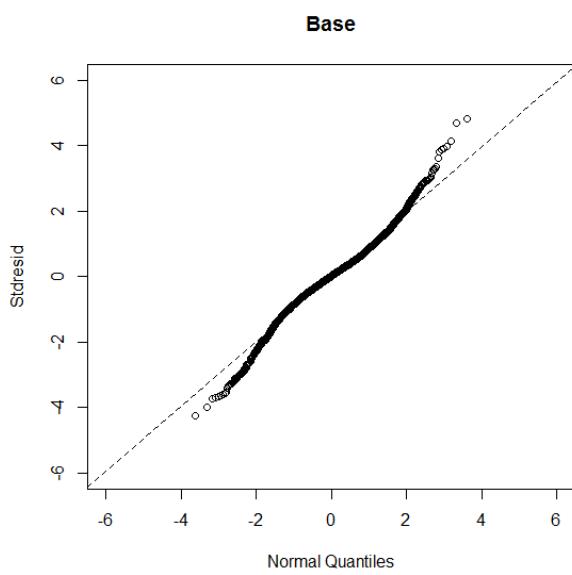

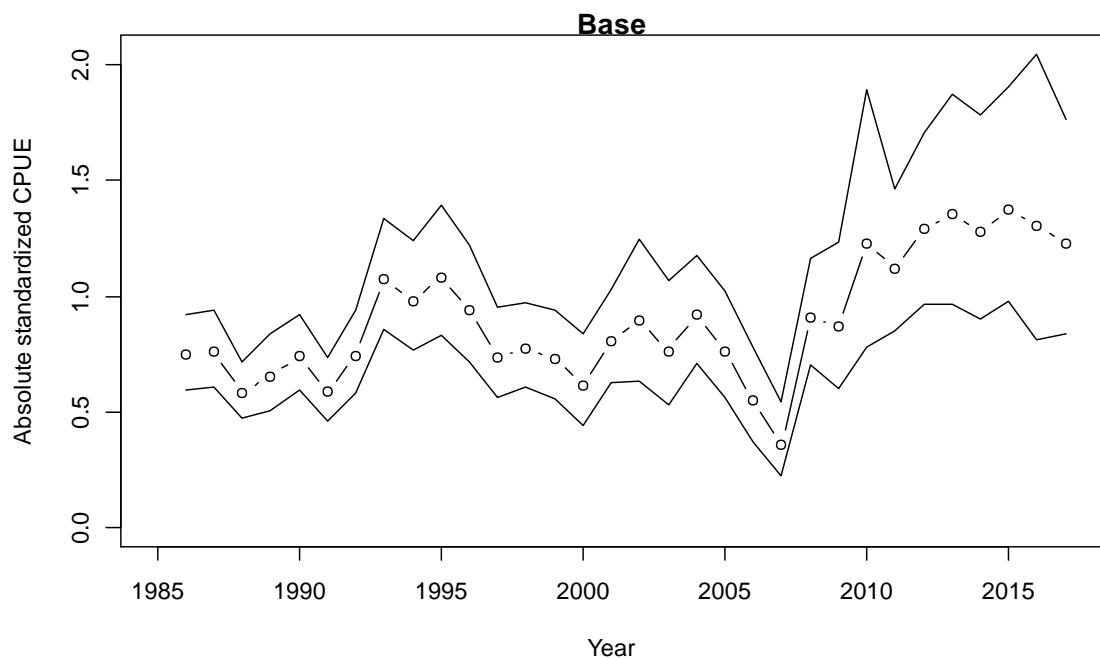

Fig. 2. Standardized CPUE (ls-mean with 95% confidence interval) of the core vessel data (upper panel) and its QQ plot of residual (lower panel) for Base case.

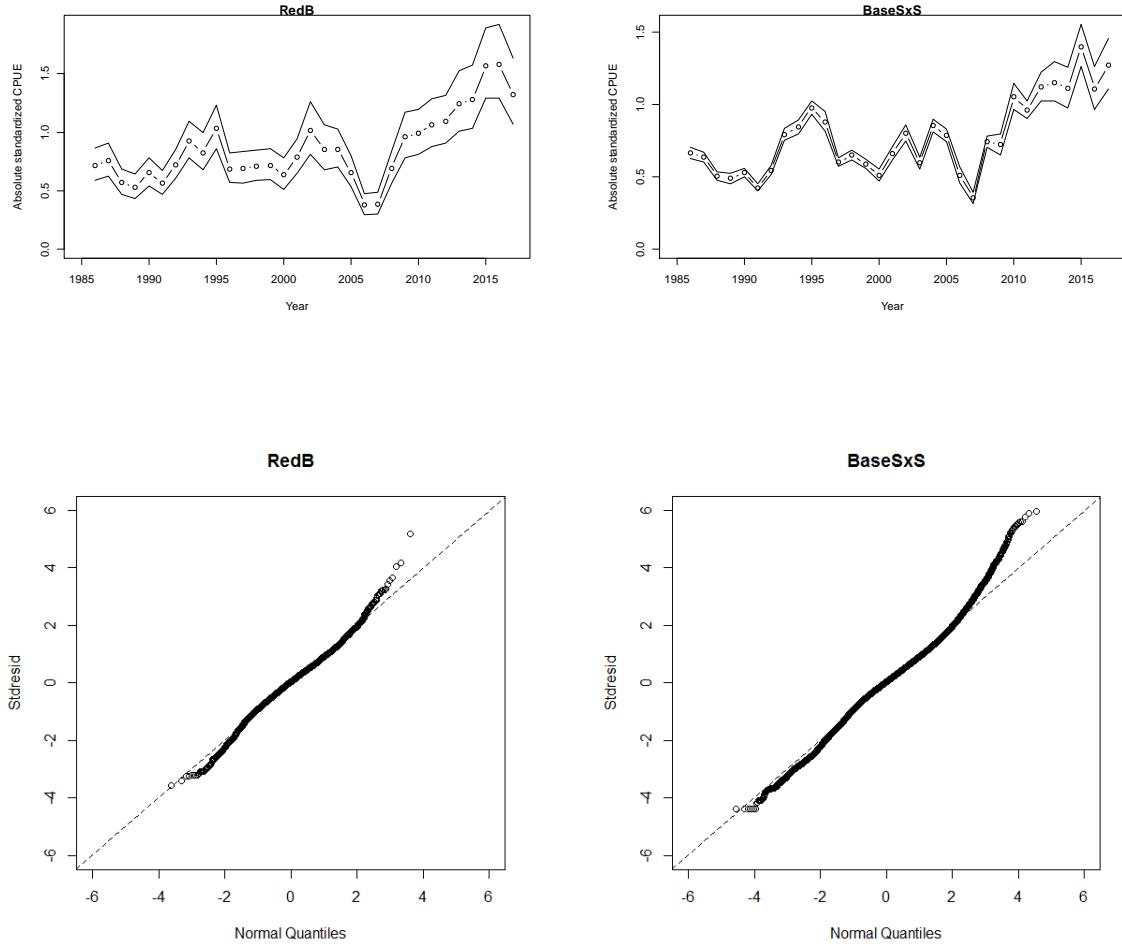

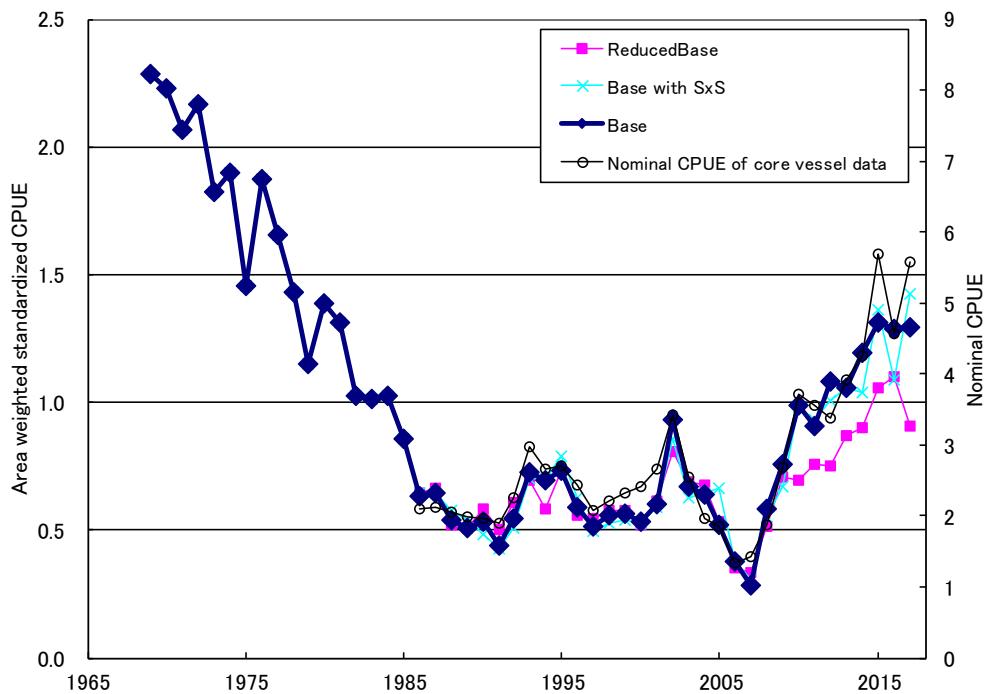

Fig. 3. Standardized CPUE (ls-mean with 95% confidence interval) of the core vessel data (upper panel) and its QQ plot of residual (lower panel) for monitoring series. Left panels for reduced base case and right panels for shot-by-shot data with base case GLM model.
