

Examination of the SBT operating model to inform conditioning and projection specifications

Hiroyuki Kurota¹, Osamu Sakai¹, and Doug S Butterworth²

¹National Research Institute of Far Seas Fisheries, ²University of Cape Town

Stock assessments and constant catch projections have been conducted using the Operating Model (OM) specified at the CCSBT technical meeting held in Seattle in July 2009. The current analysis shows that:

- (1) for the base case, higher steepness and lower M_{10} (natural mortality at age 10) are preferred in the grid sampling based on the likelihood (in contrast to the prior-based weight for steepness), and this leads to more optimistic future projections despite lower current spawning biomass (3.7% of the unfished biomass for the likelihood-based and 4.9% for the prior-based approaches),
- (2) when incomplete mixing of fish tagged is taken into consideration, the model fit, particularly to tag recaptures, is improved, and projection results are somewhat more optimistic,
- (3) the low recruitment estimate in 2006 seems to be primarily a consequence of LL1 catch-at-size data from 2008,
- (4) when CPUE is not adjusted for overcatch (i.e., $S = 0$), lower steepness and higher M are preferred, and higher S scenarios generally lead to more optimistic projection results despite worse fit to observed CPUE series, and
- (5) several sensitivity trials which accord less reliability to the Japanese longline CPUE favour higher M values and lead to more pessimistic results.

コンディショニングと将来予測の様式を決めるためのオペレーティングモデルの解析

黒田 啓行・境 磨・ダグ バタワース

2009年7月のシアトル技術会合で決められたオペレーティングモデルを用いて、資源評価と漁獲量一定の条件下での将来予測を行った。結果は以下の通り。

- (1) ベースケースにおいて、尤度に基づくグリッド・サンプリングをした場合、事前分布に基づくサンプリングをした場合に比べて、高いスチープネスと低い M_{10} (10歳での自然死亡率) が選択される。またこの場合、現在の資源量の推定値はより低くなるが（尤度ベースの場合、初期資源量に対して 3.7% だが、事前分布ベースの場合、4.9%）、将来予測はより楽観的になる。
- (2) 標識魚の混合が不完全な場合を考慮すると、モデルの適合度（特に標識再捕数へのフィット）は改善され、将来予測の結果は幾分楽観的になる。
- (3) 2006年の低い加入推定値は、主に2008年のLL1 サイズ別漁獲量データによってもたらされているようだ。
- (4) 過剰漁獲に対してCPUEを補正しない場合（すなわち S が 0 の場合）、低いスチープネスと高い自然死亡率が選択される。また S が高いほど楽観的な将来予測結果が得られるが、CPUEへのフィットは悪くなる。
- (5) いくつかの感度分析結果によると、日本の延縄CPUEデータへの信頼度を下げるようなシナリオでは、自然死亡率は高くなり、より悲観的な将来予測結果になる。

Introduction

The CCSBT Extended Scientific Committee (ESC) meeting held in September 2008 decided to update the conditioning for the Operating Model (OM) to provide the basis for advice on TACs in 2009 when used to provide constant-catch projections (CCSBT, 2008). The OM technical meeting held in Seattle in July 2009 determined most of the final specifications of OM to be used at ESC in September 2009 (CCSBT, 2009). However, some issues relating to finalizing the OM structure and projection specifications were not fully examined due to time constraints. In this paper, we show conditioning and projection results for the base case and sensitivity trials that were specified at the Seattle meeting, and report in particular on (1) higher steepness in the case of likelihood-based weight in the grid sampling, (2) incomplete mixing of fish tagged in the GAB (Great Australian Bight), (3) the low recruitment estimate for the 2006 cohort, and (4) several assumptions regarding Japanese longline CPUE series.

Data and model specification

In this analysis, we used several programs and input files (distributed by Ana Parma on 10 August 2009): “sbmod22.exe” and “sbtdat2008.dat” for the conditioning, “sample_v4.exe” for the grid sampling, and “sbtprojv117.exe” for the projection. Constant catch projections were conducted over 27 years (from 2009 to 2035) under alternative six catch levels: 0t, 7810t, 9810t, 11810t (the TAC in 2009), 13810t, and 15810t. Quota allocations by fishery were based on quota allocation by country in 2009 as follows: LL1: 0.3963, LL2: 0.096, Indonesia 0.0639, Australia 0.4439. The default grid specification proposed at the Seattle meeting in July 2009 (Table 1a) and an alternative grid with likelihood-based weight for steepness (Table 1b) were applied for all scenarios. In addition, the case of prefixed weights for M_1 and M_{10} equal to the priors (Table 1c; Case 10-1 of the sensitivity trials) and a grid with a higher value of steepness and a lower value of M_{10} (Table 1d; Case 10-2) were explored.

We examined all sensitivity trials that were specified at the Seattle meeting (Cases 1-10 in Table 2; see Appendix for the all results). We also explored some additional trials mainly to examine model behavior: the issue of low recruitment in 2006 (Case 11), impacts of the change of CPUE series (from five traditional series to a new series), and exclusion of recent CPUEs in 2007 and 2008 (Case 12).

Results and Discussion

Grid weighting of steepness and natural mortalities

When the default grid specification, where steepness weight is based on the prior, is applied, the current spawning biomass is estimated to be 4.9% of the virgin unfished biomass (Table 3a). Future projections show that spawning biomass would continue to decline under the current

catch level (Fig. 1a, left panels).

On the other hand, when the grid weight of steepness is based on likelihood, higher steepness along with lower M_{10} are preferred compared to use of the default grid weights as noted at the Seattle meeting (Fig. 1a, right panels). This case gives rise to lower current biomass (3.7% of the unfished biomass; Table 3b), but shows more optimistic future projection results, because higher steepness reverses the downward trend in stock abundance with greater certainty (Fig. 2). Likelihood components for observed data sources indicate that higher steepness leads to better fits to catch-at-size of LL3 and Indonesian fisheries, but a worse fit to LL4 size composition (Table 4).

Grid sampling based on prefixed weights for M_1 and M_{10} (Case10-1) provides recruitment and stock abundance estimates with wider variances as expected. However, the general stock trend is not substantially different (slightly more pessimistic future in the case of likelihood-based weight for steepness) from that for the current base case (Table 3).

When we explored a grid specification with a higher steepness (0.9) and a lower M_{10} (0.04) (Case 10-2), the high steepness was scarcely sampled based on likelihood (Fig. 1b). However, the low M_{10} was sampled moderately. This indicates that it might be necessary to expand the M_{10} range to lower values. Interestingly though the stock trajectories were not generally different for the likelihood-based grid sampling (Table 3). This might be related to negative correlations between M_{10} and steepness and/or between M_{10} and other estimated M_s (M_4 and M_{30}) as indicated in Table 5.

Incomplete mixing of tagged fish

Incomplete mixing between fish tagged in the GAB and untagged fish was taken into account by increasing the apparent F on tagged fish caught by Australian fishery. When the degree of incomplete mixing is fixed at 1.245 (the mid-point of a default parameter range of 0.99 and 1.5) (Case 9-1), grid sampling prefers higher M_1 and projection results are somewhat more optimistic.

When the degree of incomplete mixing is directly estimated under a default condition (Case 9-2), the estimate was constrained by the upper bound of the parameter range (1.5) in all cases (therefore, this case amounts to the same as a condition that the degree of incomplete mixing is fixed at 1.5). The model fit, particularly to tag recaptures, is greatly improved (Table 5). This case leads to slightly lower steepness, higher M_1 and more optimistic projections (Fig. 1c). As an exploratory analysis, we expanded the parameter range of the incompleteness to 5.0 and re-estimated it (Case 9-3). The result showed that the degree of incompleteness is around 2.4 (median: 2.37, 10%-ile: 2.02, 90%-ile: 2.59). It is notable that the higher M_1 is sampled together with lower steepness in most cases, and recruitment estimates become much larger (Fig. 1d).

Low recruitment in 2006

Recruitment (age-0 abundance) in 2006 is estimated to be very low (relative to recruitment

estimated from spawning stock biomass) in all cases including the base case, although the estimation uncertainty is large. It is noteworthy that 2006 is the last year to estimate recruitments directly from observed data without correlation to recruitments in previous years. At first, we expected that data relating to surface fishery influenced this recruitment estimate. After some exploratory analyses, however, we found that when sample size of catch-at-length of LL1 in 2008 was reduced (Case 11-3; Fig. 1e), recruitment in 2006 became higher (i.e., the stock-recruitment residual became close to zero), while recruitment in 2005 became lower.

Future recruitments that are uncorrelated to historical estimates from the conditioning lead to higher recruitments in the near future and somewhat quicker recovery of abundance (Case 2).

Overcatch-related issues

An alternative overcatch scenario (L2; longer and larger overcatch assumed) shows somewhat different results: slightly higher steepness, a greater current spawning biomass and more optimistic future projections (Cases 1-2, 1-3, 1-5; Table 3). The model fit is not appreciably different from that for the L1 assumption.

CPUE adjustment, the so-called S issue, also has impacts (Cases 1-1, 1-4, 1-6). In particular, there is a relatively large difference between the C0 ($S = 0\%$) and C1 ($S = 25\%$) scenarios. Generally, as S is set larger, steepness becomes higher and M_{10} lower. The current biomass becomes larger and the future projections are a little more optimistic (Table 3). This summary result is different from that obtained in 2008 (Kurota and Butterworth, 2008), but shows similarity to the result in 2006 (Kurota et al., 2006). Generally, the model fits to CPUE were poor for the C2 and C3 scenarios ($S = 50\%$ and 75%).

Other CPUE-related trials

Truncation of CPUE series in 1992 (Case 4) has a substantial impact on conditioning and on projection results (Fig. 1f). Steepness is much smaller (but nevertheless larger than for the default prior), and M_1 and M_{10} become larger than those for the base case. This gives rise to a very low current spawning biomass (about 2% of the virgin biomass) and far more pessimistic future projections. When the weight of CPUE data in the likelihood was reduced by increasing the CV to 0.3 (Case 8), the recent biomass decline (indicated by B2009/B2000) is more severe and future stock abundance continues to decline slowly under the current catch level (Table 3). These two scenarios suggest that data other than Japanese longline CPUE favour a downward trend of stock abundance. When CPUE is separated into two time series changing in 1986 (Case 6), the result is not appreciably different from the base case result with likelihood-based weights for steepness.

When a low omega value (0.75; the omega value relates to the non-linearity of the CPUE vs abundance relationship) is assumed (Case 7), lower steepness and higher M_{10} are preferred.

Together with Case 4, this run leads to a further recent decline of stock abundance even after 2000 and very pessimistic future projections.

An alternative CPUE series “Run 3” with more stable behavior in 1986-2006 (Case 5-1) shows more optimistic projection results. The goodness of model fit is almost the same as for the base case (Table 5). On the other hand, a more fluctuating “Run 6” series (Case 5-2) shows about the same projection result as the base case, while the model fit to CPUE is worse in most scenarios. We also explored a lower omega value (0.75) for these two additional CPUE series along with the default series to follow a proposal at the Seattle meeting (CCSBT, 2009). However, there was little support for the lower value in all the series based on the likelihood (Fig. 3).

The traditional five CPUE series used for the previous stock assessments give rise to more optimistic projections (Case 12). In addition, CPUEs in two recent years (2007 and 2008) seem to include information to make future projections more optimistic, though the ESC decided to exclude these two-years’ data as input to be used for the 2009 stock assessment (CCSBT, 2008). The change of CPUE series might be one of the reasons why stock status perception becomes more pessimistic in the current analysis.

Adding the troll survey index

Incorporating troll survey data (Case 3) increases recent recruitment estimates, particularly for 2007 and 2008 (Fig. 1g). This leads to rapid recovery of spawning stock biomass after 2017. This is related to the fact that recent trolling indices are quite high, and that at the present time (2009) there is no other information to estimate the recruitments in 2007 and 2008.

Excluding the aerial survey index

While we examined the reasons of low recruitment in 2006, we incidentally noticed that aerial survey index had somewhat large impacts on conditioning and projection results (Case 11-1). In particular, excluding these data leads to higher recruitments in the 1990s and larger spawning biomass in the future. It must be pointed out that this OM fits the time series for the aerial survey poorly (CCSBT, 2009), but this index does influence the assessment results to a certain degree.

Table 2. The list of sensitivity trials conducted in this analysis.

Case	Scenarios and assumptions
Base Case	C1S1L1 (CPUE scenario $S = 25\%$, LL1 scenario based on Case1 of Japanese Market Report (JMR))
Case 1	Change the LL1 scenario or effects of overcatch on CPUE.
Case1-1	- C0S1L1 (CPUE scenario $S = 0\%$)
Case1-2	- C0S1L2 (CPUE scenario $S = 0\%$, LL1 scenario based on Case2 of JMR.)
Case1-3	- C1S1L2 (CPUE scenario $S = 25\%$, LL1 scenario based on Case2 of JMR.)
Case1-4	- C2S1L1 (CPUE scenario $S = 50\%$)
Case1-5	- C2S1L2 (CPUE scenario $S = 50\%$, LL1 scenario based on Case2 of JMR.)
Case1-6	- C3S1L1 (CPUE scenario $S = 75\%$)
Case1-7	- C3S1L2 (CPUE scenario $S = 75\%$, LL1 scenario based on Case2 of JMR.)
Case 2	Projected recruitment deviates uncorrelated to historical estimates from conditioning.
Case 3	Include troll survey data.
Case 4	Truncate CPUE series in 1992.
Case 5	Substitute alternative CPUE series.
Case5-1	- Based on the alternative CPUE series Run3.
Case5-2	- Based on the alternative CPUE series Run6.
Case 6	Break CPUE into two time series, the second starting in 1986.
Case 7	Omega value of 0.75 (CPUE non linearity factor).
Case 8	Increase the lower bound on CPUE CV to 0.30.
Case 9	For modeling the tagging data component:
Case 9-1	- Increase the season-1 F 's (H) to 1.245.
Case 9-2	- Estimate the season-1 F 's (H) (default = increase the season-1 F 's (H) to 1.5).
Case 9-3	- Estimate the season-1 F 's (H) (expand the parameter range).
Case 10	Change Grid specifications of steepness and M
Case 10-1	- Use prior for M_I and M_{Io} as the simulation weight for grid integration.
Case 10-2	- Change the grid range : steepness: (0.55, 0.73, <u>0.90</u>) and M_{Io} : (<u>0.04</u> , 0.07, 0.10)
Case 11	Exploring a reason of low recruitment for the 2006 cohort:
Case 11-1	- Exclude aerial survey data.
Case 11-2	- Change the sample size of surface fishery in 2008 to zero.
Case 11-3	- Change the sample size of LL1 fishery in 2008 to zero.
Case 11-4	- Change the LL1 selectivity blocks in 2006, 2007 and 2008 to that with CV = 1.0.
Case 12	Based on old CPUE series (Nominal, Laslett, ST-windows, w0.5, w0.8):
Case 12-1	- Set the last CPUE year in fit to 2008.
Case 12-2	- Set the last CPUE year in fit to 2006.

Table3. Summary results of conditioning and projection under the current catch for the base case and sensitivity trials (note that green-shaded and grey-shaded values represent 20% more than and less than the base case results, respectively).

Figure 2. Conditioning and projection results under the current catch for different steepness values in the base case.

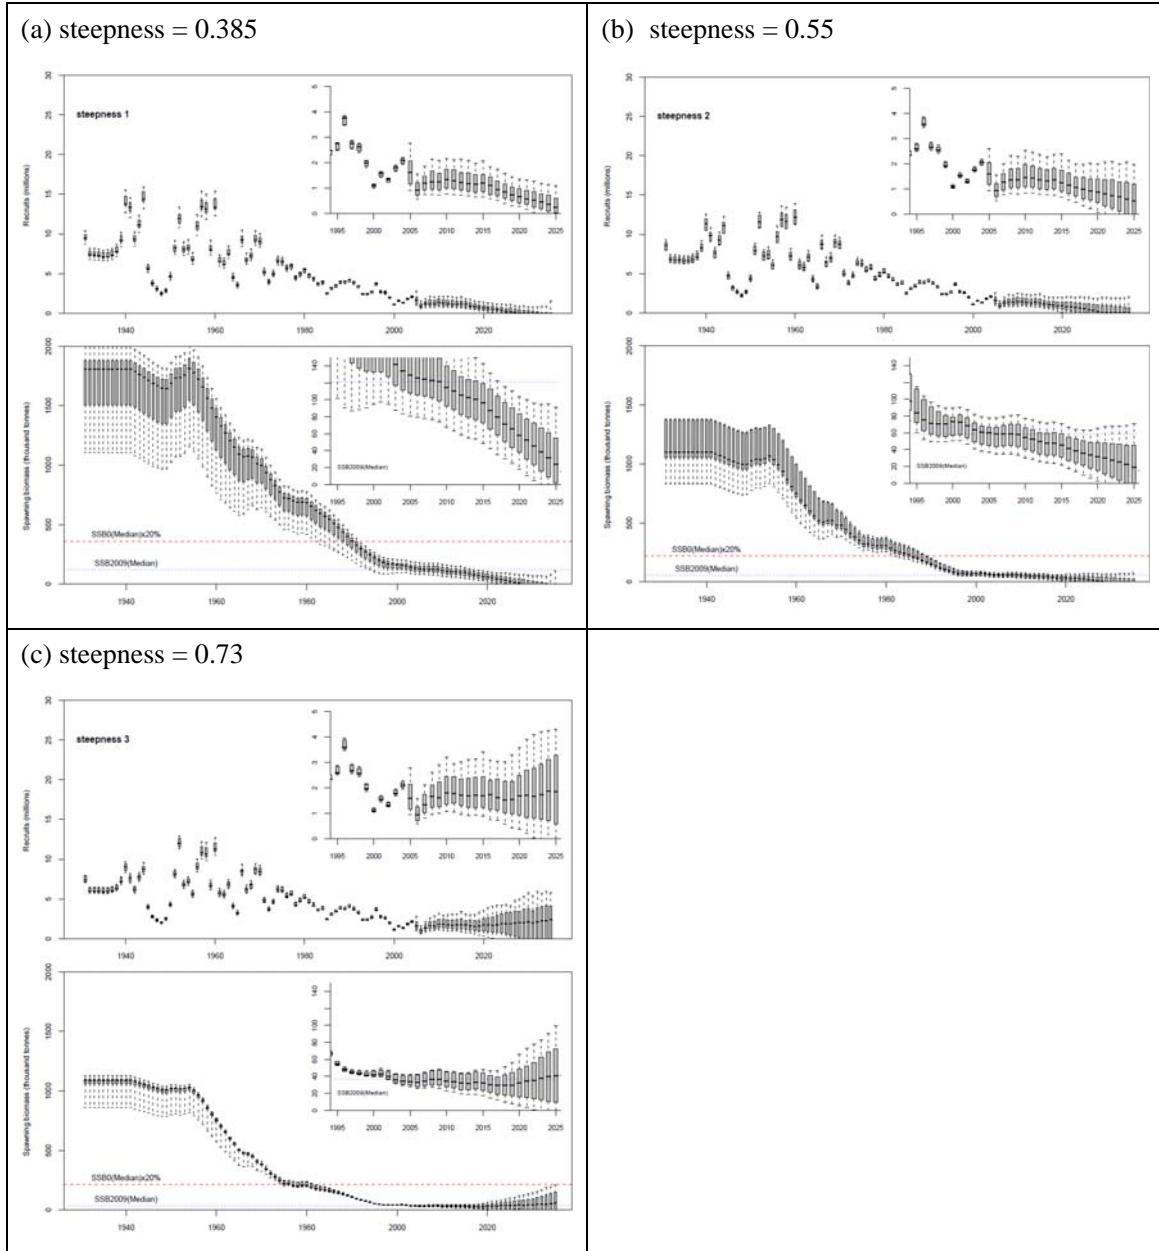

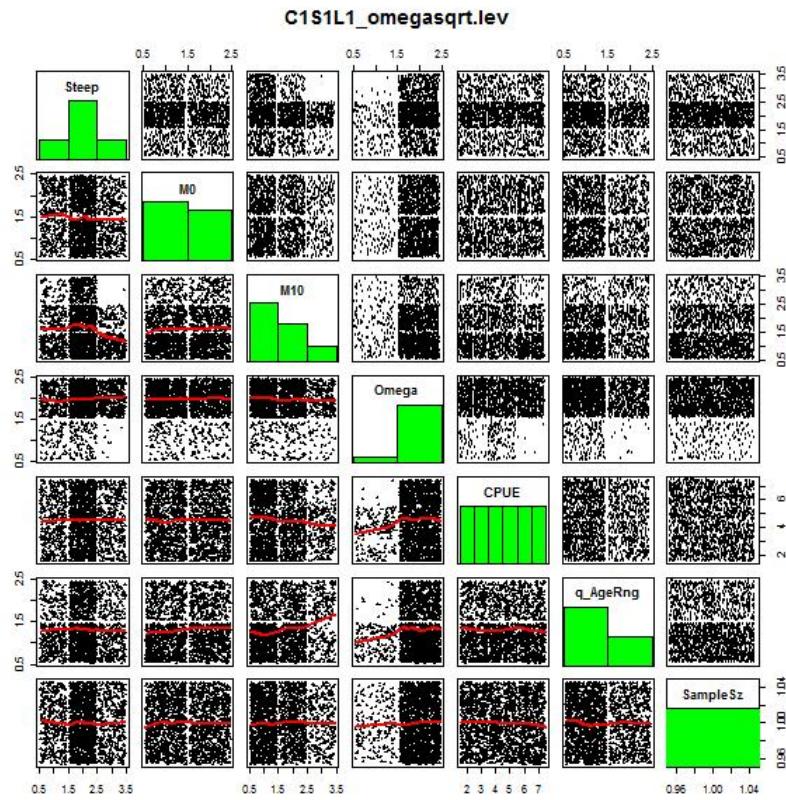

Figure 3. Estimated distributions for each uncertainty axis for six different CPUE series in the base case and Case 5: default (w0.8), default (w0.5), Run3 (w0.8), Run3 (w0.5), Run6 (w0.8), Run6 (w0.5).

Appendix: Examination of the SBT operating model to inform conditioning and projection specifications.

Table 1. The list of sensitivity trials.

Case	Scenarios and assumptions
Base Case	C1S1L1 (CPUE scenario $S = 25\%$, LL1 scenario based on Case1 of Japanese Market Report (JMR))
Case 1	Change the LL1 scenario or effects of overcatch on CPUE. <ul style="list-style-type: none"> - C0S1L1 (CPUE scenario $S = 0\%$) - C0S1L2 (CPUE scenario $S = 0\%$, LL1 scenario based on Case2 of JMR.) - C1S1L2 (CPUE scenario $S = 25\%$, LL1 scenario based on Case2 of JMR.) - C2S1L1 (CPUE scenario $S = 50\%$) - C2S1L2 (CPUE scenario $S = 50\%$, LL1 scenario based on Case2 of JMR.) - C3S1L1 (CPUE scenario $S = 75\%$) - C3S1L2 (CPUE scenario $S = 75\%$, LL1 scenario based on Case2 of JMR.)
Case 2	Projected recruitment deviates uncorrelated to historical estimates from conditioning.
Case 3	Include troll survey data.
Case 4	Truncate CPUE series in 1992.
Case 5	Substitute alternative CPUE series. <ul style="list-style-type: none"> - Based on the alternative CPUE series Run3. - Based on the alternative CPUE series Run6.
Case 6	Break CPUE into two time series, the second starting in 1986.
Case 7	Omega value of 0.75 (CPUE non linearity factor).
Case 8	Increase the lower bound on CPUE CV to 0.30.
Case 9	For modeling the tagging data component: <ul style="list-style-type: none"> - Increase the season-1 F's (H) to 1.245. - Estimate the season-1 F's (H) (default = increase the season-1 F's (H) to 1.5). - Estimate the season-1 F's (H) (expand the parameter range).
Case 10	Change Grid specifications of steepness and M <ul style="list-style-type: none"> - Use prior for M_I and M_{Io} as the simulation weight for grid integration. - Change the grid range : steepness: (0.55, 0.73, 0.90) and M_{Io}: (0.04, 0.07, 0.10)
Case 11	Exploring a reason of low recruitment for the 2006 cohort: <ul style="list-style-type: none"> - Exclude aerial survey data. - Change the sample size of surface fishery in 2008 to zero. - Change the sample size of LL1 fishery in 2008 to zero. - Change the LL1 selectivity blocks in 2006, 2007 and 2008 to that with CV = 1.0.
Case 12	Based on old CPUE series (Nominal, Laslett, ST-windows, w0.5, w0.8): <ul style="list-style-type: none"> - Set the last CPUE year in fit to 2008. - Set the last CPUE year in fit to 2006.

Table 2. Summary results for grid simulation in the base case scenario (steepness = 0.385, 0.55 or 0.73, $M_I = 0.3$, $M_{Io} = 0.07, 0.1$ or 0.14 , CPUE=w0.8, q age-range=4-18)
